High Crash Locations Methodology for Ramps, Adjacent Intersections and Ramp Terminals along the Crossroads

HIGH CRASH LOCATION ANALYSIS METHODOLOGY FOR RAMPS, ADJACENT INTERSECTIONS & RAMP TERMINALS ALONG CROSSROADS

Identification of High Crash Locations along freeway ramps, ramp terminals, and adjacent intersections along the crossroads involved:

- A spatial cluster analysis using ArcGIS, and
- A review of the crash summary reports provided by MDOT SHA's Office of Traffic and Safety for the historical crashes between January 1, 2016, and December 31, 2018.

Crashes exclusive to crossroad segments, intersections, and ramps were plotted using the latitude and longitudinal points included in the historical crash data spreadsheets provided by MDOT SHA. Using the Buffer tool, the plotted crashes were clipped to only include crashes within the Study limits in the spatial cluster analysis. To define crashes as an intersection or segment related crash, the Integrate tool was run to join all crash points within a specific tolerance of one another utilizing a 100-foot tolerance for roadway segments and a 250-foot tolerance for intersections. Finally, the Collect Events tool was used to group the crash points into a single feature point from which the total number of crashes can be derived for a specific location to help identify locations with more than 20 crashes. Ramp crashes were grouped manually. Once the high crash locations were determined, the detailed crash data provided by MDOT SHA was reviewed to determine specific crash type patterns and time of day patterns.

The high crash ramp locations developed through this process include:

1) I-270 NB Exit Ramp to I-370
2) I-270 SB Exit Ramp to Shady Grove Rd / Omega Dr
3) I-270 NB Exit Ramp to Shady Grove Rd / Redland Blvd
4) I-270 Exit Ramp to MD 28 WB
5) I-270 SB Exit Ramp to Montrose Rd EB

The high crash ramp terminals and adjacent intersections along crossroads developed through this process include:

1) MD 119 at Sam Eig Highway Intersection
2) I-270 NB Ramp Terminal at Shady Grove Road
3) Shady Grove Road at Choke Cherry Road Intersection
4) Wootton Parkway at Seven Locks Road Intersection
5) Wootton Parkway at Tower Oaks Boulevard Intersection
6) Montrose Road at Tower Oaks Boulevard Intersection
7) MD 187 at Tuckerman Lane Intersection
8) MD 355 at Grosvenor Lane

Note that the Montrose Road at Tower Oaks Boulevard intersection has less than 20 crashes (specifically 16) but is included in the high crash locations list due to a significant rear end (7 crashes) and angle (5 crashes) crash pattern.

Methodology Supporting Information

ISATe ROADWAY SEGMENTATION

The mainline freeway within the Study corridor is segmented per ISATe input requirements to develop roadway sections with consistent cross-sectional, roadside, ramp access, and traffic volume characteristics. Due to the length of the Study corridor, the ISATe analysis was conducted across multiple ISATe spreadsheet files that produced multiple ISATe output reports. Specifically, the Output Summary and Evaluation Site Summary reports which are included in this Appendix. The table below may be used to reference which ISATe output report to review for a specific section of freeway as well as to determine specific facility types within each analyzed freeway section.

General notes on the mainline freeway segmentation.

- Freeway segment limits include both directions of travel.
- The General Purpose (GP) lane segments run from the mid-point of the upstream interchange to the mid-point of the subject interchange. This does not apply to Sections 1, 15, and 20 which include the Speed Change Lanes for the interchanges at MD 117, VA 193 and MD 355.
- Ramp segments include the GP and HOT lane ramps within the interchange.
- Collector-distributor (CD) segments and Ramp segments (including GP and HOT lane facilities) are analyzed in ISATe within the same worksheet. Therefore, the results are combined.

ISATe TRAFFIC VOLUME INPUT ADJUSTMENT SEGMENTS

Below are the segments where the number of lanes exceed the maximum allowable input within ISATe and therefore, the average daily traffic volume was adjusted. See section 7.6 for more details on the volume adjustment process.

I-270 No Build

- 0.97-mile section from Montrose Road to I-270 Y – MP 2.67 to 3.64
- 4.70 miles of C-D Roads along I-270 with three lanes

I-495 No Build

- 0.41-mile section from MD 190 to I-270 West Spur – MP 3.25 to 3.66

I-270 Preferred Alternative

- 0.53-mile section from I-370 to Shady Grove Road – MP 8.54 to 9.07
- 0.42-mile section from Shady Grove Road to Gude Drive – MP 7.79 to 8.21
- 0.10-mile section from Gude Drive to MD 28 – MP 6.47 to 6.57
- 0.81-mile section from MD 28 to MD 189 – MP 5.66 to 6.47
- 0.24-mile section from Montrose Road to I-270 Y – MP 2.65 to 2.89
- 0.69 miles of C-D Roads and ramps with three lanes

I-495 Preferred Alternative

- 0.23-mile section from MD 190 to I-270 West Spur – MP 3.68 to 3.91
- 0.30 miles of C-D Roads and ramps with three lanes

Safety Performance Function for Managed Lanes

VDOT Memo on the Development of Safety Performance Functions (SPFs) for I-495 Express Lanes

MEMORANDUM

Subject: Development of Safety Performance Functions (SPFs) for I-495 Express Lanes

Introduction

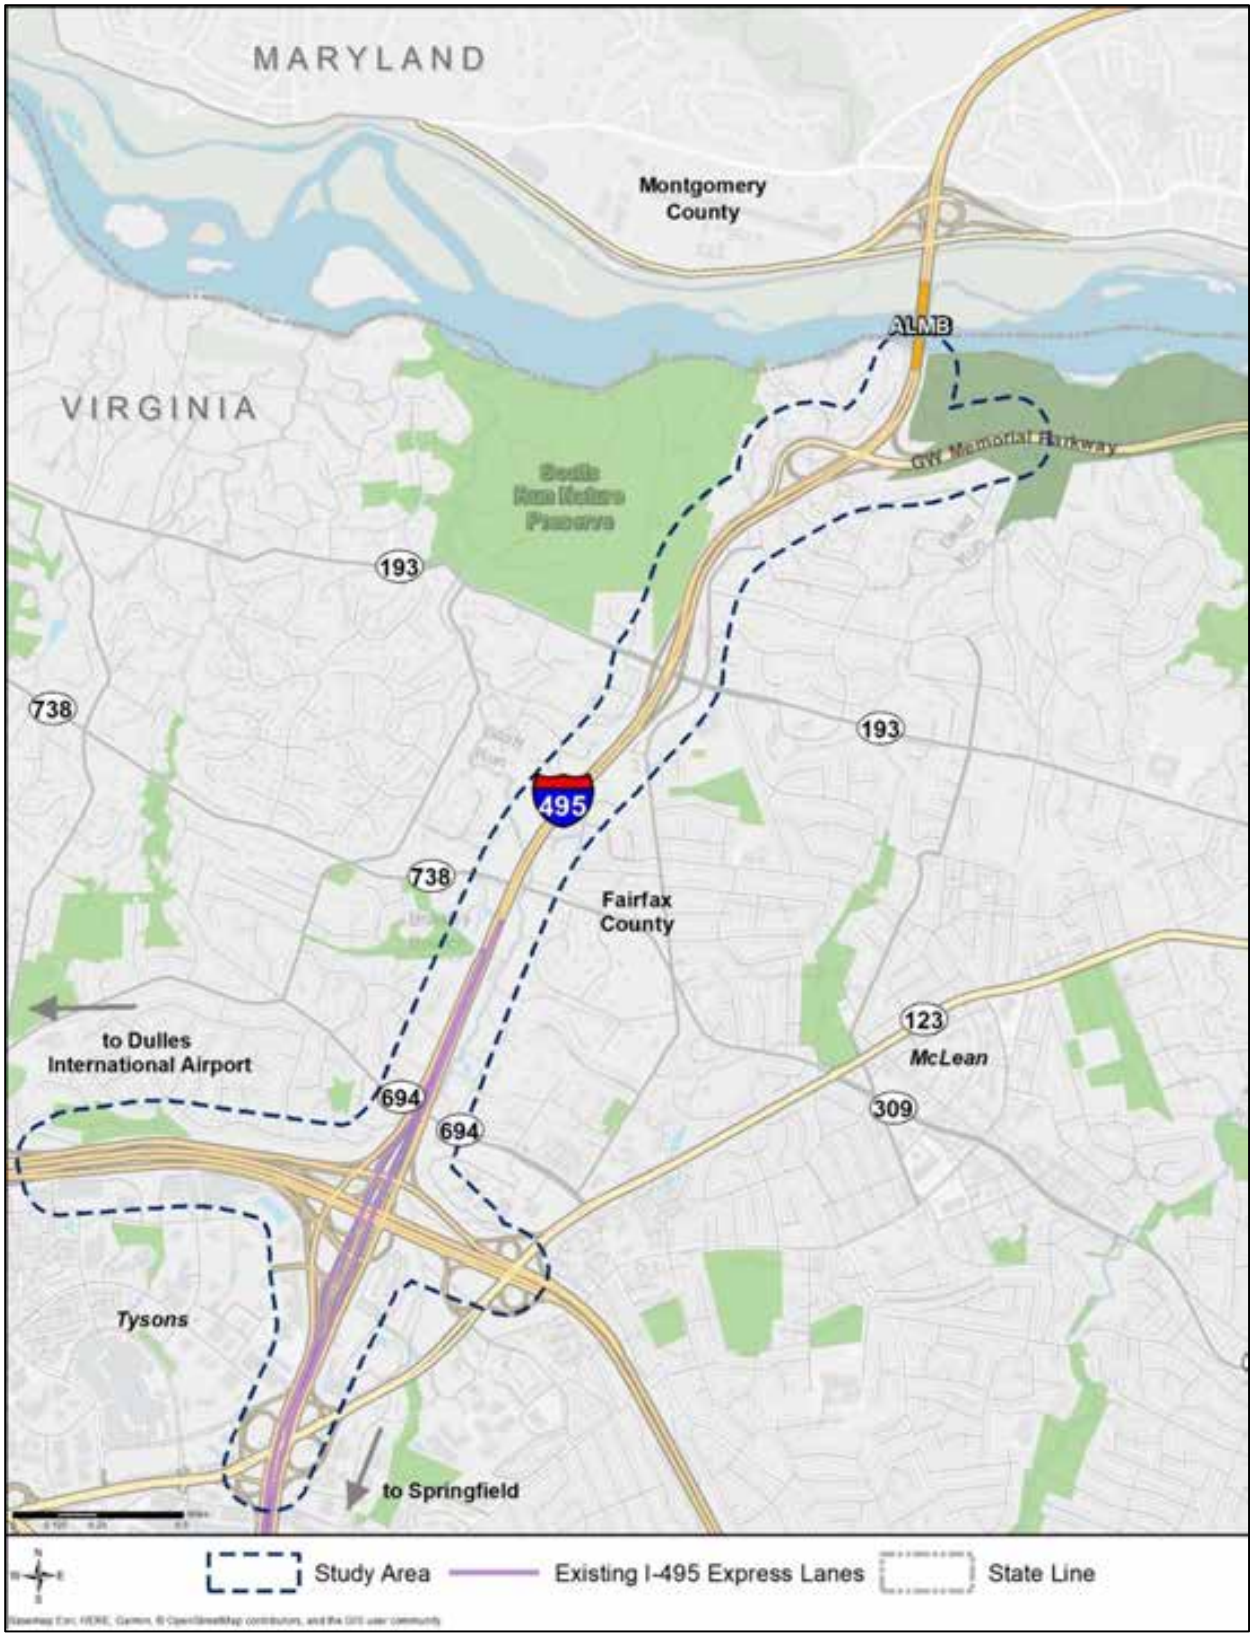
This memorandum documents the development a new Safety Performance Functions (SPFs) for Express Lanes that was conducted as part of the I-495 Express Lanes Northern Extension Project. The methodology followed the framework that had been proposed in the memo dated November 15, 2018, which was submitted to and accepted by FHWA and VDOT.

Framework and Methodology for the Development of SPFs and Crash Prediction for Express Lanes

Treatment of Freeway Segments:

The Highway Safety Manual (HSM), first edition, does not have a crash prediction methodology for estimating the safety performance of separated express lanes or urban interstate corridors with express lanes/managed lane facilities. At the time that safety analyses were conducted for I-495 and for I-66, there was insufficient experience with express lanes in Virginia to properly predict crashes for express lanes. During the conduct of the I-495 Express Lanes Northern Extension study, it was proposed to VDOT and FHWA that sufficient crash history associated with express lanes on I-495 (the Capital Beltway) and that SPFs could be developed to help predict the expected crashes on both existing and new express lanes. With the development and application of SPF for express lanes, a more complete assessment could be performed for the safety performance of both the no-build and build alternatives related to extending the I-495 Express Lanes north to the American Legion Memorial Bridge. Using historical and available crash data, traffic volume data and roadway geometric data for the existing segments of I-495 Express Lanes, a SPF was developed. The SPFs will allow for estimation of future year crash experience for both existing express lane sections on I-495 and for new express lane sections that will be included in the Build alternative.

The study area includes approximately 3.5 miles along I-495 between the Route 123 interchange and the Maryland state line at the American Legion Memorial Bridge. The study area also extends approximately 2,500 feet east along the George Washington Memorial Parkway. Intersecting roadways and interchanges are also included in the study area, as well as adjacent areas within 600 feet of the existing edge of pavement, as shown in Figure 1. The Express Lanes extension is shown in Figure 2.



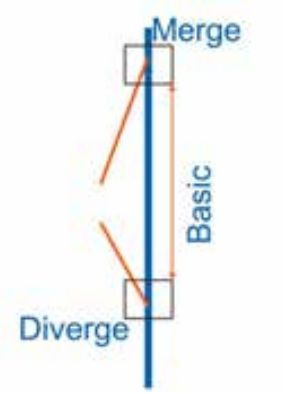


Figure 1: Express Lanes Northern Extension Study Area

Figure 2: I-495 Express Lanes Northern Extension (from Transurban Public Information Meeting, March 2018)

The construct of the safety performance prediction model was initially established to separate express lanes sections into one of three component parts, as shown below:

The Segmentation of express lanes includes: Basic Section (BS), which were between merge and diverge areas, Diverge Section (DS), which included 500 feet upstream and downstream of the diverge point, and Merge Section (MS), which included 500 feet upstream and downstream of the merge point. These are shown in the figure to the right side.

Based on this approach to segmentation, the sample size used in the development of the SPF for express lanes included the following:

<u>For Northbound Express Lanes segments</u>:

1. BS - From the Southern NB Entrance to the on-ramp from Braddock Road

It is important to note that in the development of the Safety Performance Function, the transition areas at the end of the express lanes and the ramps to/from the express lanes were excluded from the analysis. More detail on why this was done is provided in the succeeding paragraphs.

Treatment of Endings of Express Lanes:

Based on INRIX and other travel time/speed observations, free flow conditions do not always exist at the downstream ends of express lanes where drivers coming from the express lanes must merge with

adjacent traffic traveling in the general purpose (GP) lanes. Frequently, congestion occurs in this transition area due to downstream capacity limitations. Consequently, the transition zones do not operate as well as the upstream sections of the express lanes. To properly account for this, it is necessary to segregate the transition from the express lanes for the purposes of development of a SPF for express lanes. A line is needed to demark the end of the free flow, higher speed travel on express lanes and the beginning of the point where flow on express lanes is affected by downstream congestion and capacity-limitations associated with the GP lanes. Beyond the demarcation lines, ISATe is appropriate to analyze the sections of the Express Lanes that are no longer operating under free flow conditions.

Treatment of Ramps to/from Express Lanes:

No SPFs were developed for individual ramps to or from the express lanes. There were relatively few crashes reported on the ramps to/from the express lanes. Most of the crashes that occurred within the vicinity of the express lane ramps are reported in/near merges and diverges. As noted in the methodology memo, ISATe will be used to analyze the safety of express lane (EL) ramps. This will be in a manner similar to how ISATe is used to analyze ramps to and from the general purpose (GP) lanes. Consequently, ISATe procedures will be used for all EL and GP ramps for the 2025 and 2045 No-Build and Build alternatives.

Development of Safety Performance Functions for Express Lanes

In developing the safety performance functions, it is important to recognize the underlying assumptions on which the new relationships were based. These included the following:

- Because I-495 ELs operate within an uncongested regime, SPFs would be directly related to AADT as a dependent variable within certain thresholds.
- Traffic Volumes and Crash History for Existing I-495 Express Lane sections for the past 5 years (Jan. 1, 2013 through Dec. 31, 2017) were deemed adequate from a historical perspective and used to develop new SPFs for the express lanes directional segments consisting of two lanes.

The salient features of the crash data, from which the SPF were developed, are described as follows:

- A total of 396 crashes were reported over a period of 5 years on the I-495 express lanes.
- Of those 396 reported crashes, 49 reported crashes occurred within the Diverge Segments and 45 reported crashes occurred within the Merge Segments. The remaining 302 reported crashes occurred on the Basic and Weave Segments.

A series of statistical models were developed to predict crashes. The primary independent variables used in the regression analyses were AADT, segment length and segment type (Merge, Diverge or Basic/Weave). The number of predicted crashes per year was the dependent variable in each model. The following functional forms for SPFs were tested:

Group 1 (Each model included segment length as one of the independent variables):

1. All reported crashes as a function of AADT, segment length and segment type
2. All reported crashes as a function of AADT and segment length
3. Basic and weave segment crashes as a function of AADT and segment length
4. Merge segment crashes as a function of AADT and segment length
5. Diverge segment crashes as a function of AADT and segment length

Group 2 (None of the models included section length as an independent variable)

6. All reported crashes as a function of AADT and segment type
7. All reported crashes as a function of AADT
8. Basic and weave Segment Crashes as a function of AADT
9. Merge segment crashes as a function of AADT
10. Diverge segment crashes as a function of AADT

The results of the statistical regression modelling were as follows:

Group 1:

1. All Crashes as a function of AADT, segment length and segment type: Segment type was insignificant.
2. All Crashes as a function of AADT and segment length: All variables were significant.
3. Basic and Weave Segment Crashes as a function of AADT and segment length: All variables were significant.
4. Merge Segment Crashes as a function of AADT and segment length: All variables were insignificant.
5. Diverge Segment Crashes as a function of AADT and segment length: AADT was insignificant.

Group 2:

6. All Crashes as a function of AADT and segment type: AADT and segment type variables were insignificant.
7. All Crashes as a function of AADT: All variables were significant.
8. Basic and Weave Segment Crashes as a function of AADT: All variables were insignificant.
9. Merge Segment Crashes as a function of AADT: All variables were insignificant.
10. Diverge Segment Crashes as a function of AADT: All variables were insignificant.

The results of the statistical modelling results and the statistical model forms are included in an appendix at the end of this memo. The results show that SFP2 in Group 1 and SPF7 in Group 2 were the only models in which all of their independent variables were found to be statistically significant. Of the two, SFP2 in Group 1 had a much higher R-squared value, which reflects a better "goodness of fit," compared to SPF7 in Group 2. Intuitively, predicted crashes should have a direct correlation to AADT and roadway segment length. The models in the Highway Safety Manual for crash prediction are also very similar in form but with different coefficients.

On the basis of the analysis conducted, the proposed SPF for express lanes on I-495 is given below for the non-linear and linear regression models.

Non-Linear Regression: Expectation ($Crashes_{i,t}$) = exponential (0.011022579 + 0.987113593 * ln($Segment\ Length_{i,t}$) + 0.141283034 * ln($AADT_{i,t}$)

Linear Regression: Expectation ($Crashes_{i,t}$) = 0.550840245 + 4.130999289 * $Segment\ Length_{i,t}$) - 0.000121228 * $AADT_{i,t}$)

Where:

$Crashes_{i,t}$ = Crashes/year on Segment i for Time period t,

$Segment\ Length_{i,t}$ = Segment Length on Segment i for Time period t and

$AADT_{i,t}$ = Average Annual Daily Traffic on Segment i for Time period t.

The non-linear regression form had an R-squared value of 0.51 and the linear regression form had an R-squared value of 0.564; therefore, the linear regression model form was chosen due to the better R-squared value. There was a challenge with linear regression model for a limited number of cases where the model had a negative prediction of crashes. To fix that challenge, the form of the linear regression model was modified to be the max value of 0 and linear regression predicted crashes; this change in the model form solved the challenge by replacing negative prediction of crashes with zero. The R-squared for the modified form continued to be 0.564.

On the basis of the analysis conducted, the proposed SPF for express lanes on I-495 is given below:

Expectation ($Crashes_{i,t}$) = Max[0.550840245 + 4.130999289 * $Segment\ Length_{i,t}$) -0.000121228 * $AADT_{i,t}$), 0]

Where:

$Crashes_{i,t}$ = Crashes/year on Segment i for Time period t,

$Segment\ Length_{i,t}$ = Segment Length on Segment i for Time period t and

$AADT_{i,t}$ = Average Annual Daily Traffic on Segment i for Time period t.

This equation applies to Merge Sections, Diverge Sections and Basic+Weave Sections. The Appendix includes a comparison of the actual crashes and predicted crashes for all segments in the existing conditions. The comparison shows the difference in the total crashes predicted using linear regression model versus actual crash performance is less than 1 crash in five years for existing conditions. The proposed SPF for I-495 Express lanes can be used for the prediction of crashes for future No-Build and Build alternatives for the I-495 Express Lanes Northern Extension project.

CRASH PREDICTION TOOLS FOR UNCONVENTIONAL INTERCHANGES & RAMP TERMINALS

Safety Performance Function for Single Point Diamond Interchange

The publication titled *Safpety Performance of Crossroad Ramp Terminals at Single-Point and Tight Diamond Interchanges* provides a Safety Performance Function for a Single Point Diamond interchange that predicts crashes based on traffic volumes on the ramps and crossroad, and number of free-flow right-turns from the exit ramps to the crossroad.

Equation

$$N_{spf,fatal\ \&\ injury} = e^{-1\ .71 + 0.88 \times \ln(AADT_{xrd}) + 0.88 \times \ln(AADT_{ramp})}$$

$$N_{spf,PDO} = e^{-15.60 + 0.61 \times \ln(AADT_{xrd}) + 1.15 \times \ln(AADT_{ramp})}$$

Where,

$N_{spf,\ fatal\ \&\ injury}$ = Predicted average fatal and injury crash frequency
$N_{spf,\ PDO}$ = Predicted average PDO crash frequency
$AADT_{xrd}$ = Annual Average Daily Traffic along the crossroad
$AADT_{ramp}$ = Annual Average Daily Traffic along the interchange ramps

Safety Performance Function for Conventional Diamond Interchange

The Highway Safety Manual, Chapter 19 Table 19-15 supplies a Safety Performance Function for a Conventional Diamond interchange that predicts crashes at each of the ramp terminals based on traffic volumes on the ramps and crossroad, intensity of development, and number of crossroads through lanes.

Equation

$$N_{spf,fatal\ \&\ injury} = e^{-2.335 + 1.191 \times \ln(0.001 \times AADT_{xrd}) + 0.131 \times \ln(0.001 \times AADT_{ex}) + 0.001 \times AADT_{en})}$$

$$N_{spf,PDO} = -2.072 + 0.879 \times \ln(0.001 \times AADT_{xrd}) + 0.545 \times \ln(0.001 \times AADT_{ex} + 0.001 \times AADT_{en})$$

Where,

$N_{spf,\ fatal\ \&\ injury}$ = Predicted average fatal and injury crash frequency
$N_{spf,\ PDO}$ = Predicted average PDO crash frequency
$AADT_{xrd}$ = Annual Average Daily Traffic along the crossroad
$AADT_{ex}$ = Annual Average Daily Traffic along the exit ramp
$AADT_{en}$ = Annual Average Daily Traffic along the entrance ramp

Crash Modification Factor for Converting Conventional Diamond to Diverging Diamond Interchange

The publication titled *Systematic Safety Evaluation of Diverging Diamond Interchanges Based on Nationwide Implementation Data* supplies a Crash Modification Factor for converting a Conventional Diamond Interchange to a Diverging Diamond.

Crash Modification Factors

CMF ID	CMF Name	CMF	Quality	Crash Severity
10762	Convert diamond interchange to Diverging Diamond Interchange or Double Crossover Diamond	0.558	****	K (fatal), A (serious injury), B (minor injury), C (possible injury)
10763	Convert diamond interchange to Diverging Diamond Interchange or Double Crossover Diamond	0.92	****	O (property damage only)
